Este projeto tem o objetivo de divulgar como desenvolver modelos para epidemias, desde sua modelagem matemática até sua concepção computacional em Python. Sendo assim composto por vídeos explicativos, notebooks em Python, e diversas visualizações, para ajudar com o entendimento do conteúdo apresentado.

CHAPTER 1

Alguns resultados do século XX...

Para exemplificar o desempenho do conteúdo apresentado, foi feita uma análise com dados do século passado do Reino Unido (United Kingdom), e utilizando os modelos aqui desenvolvidos é possível obter previsões do comportamento dos dados. Essas previsões, juntamente com os dados reais, estão apresentadas na figura a seguir:

Assim como o estudo de correlação entre os modelos SIR obtidos para cada uma das cidades durante os períodos de epidemias do Reino Unido:

CHAPTER 2

Previsões da COVID-19

Nesta análise utilizamos o modelo desenvolvido para tentar prever os comportamentos da COVID-19. Para isso, primeiramente utilizamos dados de países que já apresentam um comportamento característico da estrutura SIR e já estão no seu período de amortecimento da curva de infectados. Desta forma podemos validar o modelo com relação a sua capacidade de prever eventos futuros, mesmo que somente poucos dias de dados sejam utilizados. Desta forma algumas análises específicas, e de maior impacto, são apresentadas nessa primeira página:

- Determinação do número básico de reprodução R_0 no decorrer da epidemia
- Previsão da quantidade de infectados notificados no sistema público
- Previsão do momento de pico da epidemia

No caso, essas análises foram feitas para Itália , China e Alemanha , países que já estão em seu período de diminuição do nível de infectados. Para exemplificar a capacidade de previsão do algoritmo de aprendizado desenvolvido, nas visualizações a seguir nós mostramos a previsão feita pelo algoritmo para cada país a medida que os tempo da epidemia foi passando e mais dados foram utilizados para a aprendizagem:

Nosso modelo aprende com algoritmos de otimização os parâmetros da estrutura SIR, juntamente com a proporção da população que está sendo registrada pelo sistema de saúde. No caso, ele aprende três parâmetros fundamentais do modelo: β (contatos por dia), r (em que $1/r$ é o tempo médio de recuperação da doença), e o $S(0)$ (quantidade inicial de suscetíveis), para que a epidemia tenha o comportamento que os dados mostram. No caso os valores ajustados para cada país foram:

Caso queira tentar ajustar os parâmetros você mesmo, basta clicar no botão abaixo!

2.1 Determinação do R_0

Note que o parâmetro R_0, é determinado a partir dos dois outros parâmetros característicos do modelo SIR, $R_0 = \beta/r$. Aqui utilizamos um modelo SIR que pondera a quantidade de suscetíveis, uma vez que nem toda a população pode ser considerada suscetível, visto que nem todas as pessoas infectadas e recuperadas são notificadas ao sistema público. Além disso, nem toda a população é exposta ao vírus, devido a políticas públicas, isolamentos, etc.

Note: Desta forma, note que o modelo desenvolvido somente modela as pessoas notificadas pelo sistema de saúde, sendo assim, representativo de uma parte da verdade situação do país.

Dito isso, é possível definir os valores encontrados pelo algoritmo de aprendizagem para o parâmetro R_0 a medida que os dias da pandemia passaram:

2.2 Previsões do consumo do sistema público

Um dos parâmetros que nosso algoritmo aprende durante seu processo de treinamento é um parâmetro que pondera a quantidade da população de suscetíveis inicial (simplesmente uma técnica para melhorar o condicionamento númerico do algoritmo). Porém, como esse parâmetro tende sempre a estimar o valor de $S(0)$ igual ao valor de $R(\infty)$. Note que sempre é verdade $S(0) \geq R(\infty)$. Como os dados medidos são somente das pessoas notificadas e acompanhadas pelo sistema de saúde, podemos concluir que o valor de $R(\infty)$ é a quantidade de pessoas que foram contaminadas, frequentaram o sistema de saúde para o diagnóstico e por isso estão na base de dados. Nosso algoritmo prevê a quantidade de $S(0) = R(\infty)$, desta forma para cada novo dia de dados temos uma nova previsão de qual será a quantidade de pessoas absorvidas pelo sistema de saúde. Nos gráficos a seguir conseguimos mostrar o erro percentual entre o real valor de $R(\infty)$ e o valor estimado por nosso modelo a cada dia da epidemia:

2.3 Previsões dos picos epidêmicos da COVID-19

Nesta análise apresentamos o efeito da quantidade de dados na performance do modelo desenvolvido analisando a capacidade de prever o dia em que acontecerá o pico da quantidade de infectados da epidemia da COVID-19. Para isso estamos utilizando dados de países que já tiveram seu pico de contágio e atualmente estão no período de amortecimento da quantidade de infectados. Alguns dos países analisados foram a China , Itália e Alemanha , que possibilitaram as análises abaixo. Nestas figuras é mostrado o erro do modelo ao tentar prever o dia de pico, para cada dia da epidemia:

3.1.2 Suscetível, Infectado e Removido (Recuperado)

A proposta é introduzir um modelo determinístico para análise de evolução de uma epidemia. O modelo aqui representado foi inicialmente proposto por Kermack, W. and McKendrick, A., 1927. A contribution to the mathematical theory of epidemics. Proc. R. Soc. London A 115, 700-721. O modelo tem as seguintes premissas:

1. Uma posulação invariante no tempo com **N** individuos (fechada).
2. Taxas constantes: contato e remoção.
3. Desconsiderando variações demográficas: nascimentos e mortes.
4. População "bem misturada".

O modelo é fundamentado em três estados: **S** - suscetível, **I** - infectado e **R** - removido ou recuperado.

$$S(t) + I(t) + R(t) = N$$

[3]:
```
# Tamanho da populção - N
N = 500

# Valores iniciais
I0 = 1
R0 = 0
S0 = N - I0
```

O conjunto de equações diferenciais que caracteriza o modelo é descrito abaixo. No modelo

$$\beta - \text{representa a taxa de transmissão ou taxa efetiva de contato}$$

e

$$r - \text{a taxa de remoção ou recuperação.}$$

$$\frac{dS(t)}{dt} = -\beta S(t) I(t)$$
$$\frac{dI(t)}{dt} = \beta S(t) I(t) - rI(t)$$
$$\frac{dR(t)}{dt} = rI(t)$$

[4]:
```
# Definição do conjunto de equações diferencias não lineares que formam o modelo.

def SIRm(y, t, N, Beta, r):
    S, I, R = y
    Sdot = -(Beta * S * I)
    Idot = (Beta * S * I)  - r * I
    Rdot = r * I
    return Sdot, Idot, Rdot
```

3.1.3 Analisando a evolução de β e r

[5]:
```
# Beta -  taxa de contato,
# r - taxa média de recuperação (in 1/dia).
Beta = 0.0009
r = 1e-1

# Resolução da simulação - Escala temporal (dias)
t = np.linspace(0, 100, 1000)

# Vetor de condições iniciais
y0 = S0, I0, R0

# Integrando as Equações do modelo SIR
ret = odeint(SIRm, y0, t, args=(N, Beta, r))
S, I, R = ret.T

# Visualizando a evolução da Epidemia - S(t), I(t) e R(t)
p = figure(tools="pan,hover,lasso_select",
           x_range=(0, t[-1]), y_range=(0, N),
           plot_width=600, plot_height=400)

p.line(t, S, legend_label="Suscetíveis", color="#ffd885", line_width=3)
p.line(t, I, legend_label="Infectados",  color="#de425b", line_width=3)
p.line(t, R, legend_label="Removidos",   color="#99d594", line_width=3)

p.grid.grid_line_alpha = 0
p.ygrid.band_fill_color = "olive"
p.ygrid.band_fill_alpha = 0.1
p.yaxis.axis_label = "Indivíduos"
p.xaxis.axis_label = "Dias"
p.legend.click_policy = "mute"
p.legend.items.reverse()

show(p)
```

Data type cannot be displayed: application/javascript, application/vnd.bokehjs_exec.v0+json

Salvando o modelo

[6]:
```
import pandas as pd

output = pd.DataFrame({"S": S, "I": I, "R": R})
output.to_csv('SIRpd', index=False)

print(output)
```

```
              S         I           R
0    499.000000  1.000000    0.000000
1    498.954252  1.035561    0.010187

```

3.2.1 Configurações

[2]:
```
import numpy as np
from scipy.integrate import odeint

from bokeh.palettes import brewer, Inferno10
from bokeh.plotting import figure, show
from bokeh.io import output_notebook
from bokeh.layouts import gridplot

output_notebook()
```

Data type cannot be displayed: application/javascript, application/vnd.bokehjs_load.v0+json

3.2.2 Modelo para pequeno grupo

Há no senso comum o entendimento que há uma chance de "pegar" uma doença. Supondo que a probailidade que representa esta sensação seja $\mathbf{p}$ e que a probilidade de escapar desta doença seja $\mathbf{q}$. Vamos admitir um cenário onde tenhamos uma família de três pessoas $\mathbf{N} = 3$ e um dos individuos estaje **i**nfectado (**I**). Supondo que neste caso $\mathbf{p} = 0.4$ logo $\mathbf{q} = 0.6$. Admitindo este cenário pode-se explorar as seguintes progressões da doença (P_i - infectado e $\overline{P_i}$ - não infectado) :

Pensando em casos:

1. Apenas o primeiro **ifectado** desenvovle a doença.
2. O **infectado** transmite para um dos outros dois **suscetíveis** apenas.
3. Os dois **sucetíveis** são infectados um após o outro.
4. Ambos os **suscetíveis** são infectados simultaneamente.

Traduzindo em **cadeias** de transmissão:

1. $1 \rightarrow 0$
2. $1 \rightarrow 1 \rightarrow 0$
3. $1 \rightarrow 1 \rightarrow 1$
4. $1 \rightarrow 2$

Traduzindo em **probabilidades** de cada cadeia de transmissão:

1. $\overline{P_1}$ e $\overline{P_2}$ - $\mathbf{q^2}$
2. $\overline{P_1}$ e P_2 - $\mathbf{pq^2}$ **ou** P_1 e $\overline{P_2}$ - $\mathbf{pq^2}$
3. $\overline{P_1}$ e $P_2 \rightarrow P_1$ e P_2 - $\mathbf{p^2q}$ **ou** P_1 e $\overline{P_2} \rightarrow P_1$ e P_2 - $\mathbf{p^2q}$
4. P_1 e P_2 - $\mathbf{p^2}$

[3]:
```
p = 0.4
q = 1 - p

C1 = q**2
C2 = 2*p*(q**2)
C3 = 2*q*(p**2)
C4 = p**2

print(C1,C2,C3,C4, C3+C4, C1+C2+C3+C4)
```

```
0.36 0.288 0.19200000000000003 0.16000000000000003 0.3520000000000001 1.0
```

Considerando as probabilidades calculadas para cada uma das sequências, aplicada um cenário de 1000 famílias com três integrantes, pode-se estimar que cerca de **360** famílias, atigidas pela doença, terão apenas 1 infectado, **288** famílias terão pelo menos 1 infectado e **352** famílias todos serão infectados.

Se generalizarmos a análise pode-se dizer que o número de infectados $\mathbf{I_t}$ na próxima geração de infectados será $\mathbf{I_{t+1}}$. O termo $\mathbf{t}$ indica a geração da epidemia e indica com uma certa *imprecisão* a escala de tempo.

$$P(I_{t+1} = i_{t+1} | S_t = s_t, I_t = i_t) \sim \binom{s_t}{i_t} (1 - q_t^i)^{I_{t+1}} (q)^{i_t(s_t - i_{t+1})}, s_t \geq i_{t+1}$$

3.2.3 Generalizando o modelo

A partir da proposta que o contágio é dependente de uma probabilidade **p** de transmissão da doença, que corresponde a uma probabilidade **q** de escapar de ser contaminado, pode-se estabelecer um modelo que seja capaz de representar a cadeia de transmissão.

$$I_{t+1} \sim binomial(S(t), p)$$
$$S_{t+1} = S_t - I_{t+1}$$
$$R_{t+1} = R_t + I_t$$

Observe a semelhança com o modelo determinístico, exceto o fato do número de infectados ser um valor randômico, governado pela distribuição Binomial.

[4]:
```
# Modelo Reed-Frost
ngen  = 30;      # número de gerações
Sinit = 2000;    # população suscetível
Iinit = 1;       # infectados
Rinit = 0;       # removidos / recuperados

q = 0.999;

nsims = 2000;    # número de simulações

x, y = list(), list()
M = np.zeros((nsims-1,ngen-1))

TOOLS="zoom_in,zoom_out,save"
p = figure(tools=TOOLS, plot_width=600, plot_height=400)

for i in range(1,nsims-1):
    S = np.linspace(0,1,ngen) - np.linspace(0,1,ngen)
    I = np.linspace(0,1,ngen) - np.linspace(0,1,ngen)
    R = np.linspace(0,1,ngen) - np.linspace(0,1,ngen)
    S[1], I[1], R[1] = Sinit, Iinit, Rinit
    for j in range(1,ngen-1):
        # np.random.binomial(n, p, 1000)
        I[j+1] = np.random.binomial(S[j], 1 - q**I[j], 1);
        S[j+1] = S[j] - I[j+1]
        R[j+1] = R[j] + I[j]
        M[i,j] = I[j]

    p.line(range(ngen), I, line_width=2, color="#8e44ad", line_alpha=0.05)

p.grid.grid_line_alpha = 0
p.ygrid.band_fill_color = "olive"
p.ygrid.band_fill_alpha = 0.1
p.yaxis.axis_label = "Infectados"
p.xaxis.axis_label = "Gerações"

show(p)
```

Data type cannot be displayed: application/javascript, application/vnd.bokehjs_exec.v0+json

3.2.4 Análise dos cenários para cada geração nova de infectados

Observe que para cada nova geração a distribuição estatística varia e pode-se observar o comportamento da distribuição Binomial. Neste sentido pode-se observar quem "governa" a incerteza da evolução da epidemia. A linha pontilhada em cada histograma representa a média para cada geração.

[5]:
```
num = 10
x = np.linspace(0, 100, 1000)
pallete = Inferno10

fig_list = []
for i in range(num):
    hist, edges = np.histogram(M[:,i], density=False, bins=50)
    p = figure(tools="pan,hover,lasso_select", plot_width=300, plot_height=300)
    p.quad(top=hist, bottom=0, left=edges[:-1], right=edges[1:],
     fill_color=pallete[i], fill_alpha=0.5, line_color=pallete[i],
     legend_label="k = " + str(i) )
    p.grid.grid_line_alpha = 0
    p.ygrid.band_fill_alpha = 0.1
    p.ygrid.band_fill_color = "olive"
    p.yaxis.axis_label = "Frequ^encia"
    p.xaxis.axis_label = "Infectados"
    fig_list.append(p)

grid = gridplot(fig_list, ncols=2)
show(grid)
```

Data type cannot be displayed: application/javascript, application/vnd.bokehjs_exec.v0+json

[6]:
```
num = 15

p = figure(tools="pan,hover,lasso_select", y_axis_type="log", plot_width=600, plot_
↪height=400)

for i in range(num):
    x = (i+1) * np.ones((len(M[:,i]),))
    try:

3.3.2 O problema

O conjunto de equações diferenciais que caracteriza o modelo é descrito abaixo. No modelo $:nbsphinx-math:*beta* '- *:nbsphinx-math:*text{representa a taxa de transmissão ou taxa efetiva de contato}' $ e r – a taxa de remoção ou recuperação.

$$\frac{dS(t)}{dt} = -\beta S(t)I(t)$$
$$\frac{dI(t)}{dt} = \beta S(t)I(t) - rI(t)$$
$$\frac{dR(t)}{dt} = rI(t)$$

Gostaríamos de identificar quais parâmetros β e r resultam num melhor ajuste do modelo para os dados de **S**,**I** e **R**

[6]:
```
def SIRmodel(y, t, Beta,r):
    S, I, R = y
    Sdot = -(Beta * S * I)
    Idot = (Beta * S * I)  - r * I
    Rdot = r * I
    return Sdot, Idot, Rdot

# Resolução da simulação - Escala temporal (dias)
```

3.3.3 Obtendo $y_s(\theta, k) = [S\ I\ R]$

O trecho a seguir retorna os valores sintetizados $y_s(\theta, k) = [S\ I\ R]$ representa o dado sintetizado a partir de um modelo sintetizado para uma determinada amostra k e θ representa o vetor ed parâmetros $\theta = [\beta\ \ r]^T$. A partir de uma condição inicial y_0.

[7]:
```
def SIRsim(y0,t,theta):
    Beta = theta[0]
    r = theta[1]
    ret = integrate.odeint(SIRmodel,y0,t,args=(Beta,r))
    S, I, R = ret.T
    return S, I, R
```

3.3.4 Condições inicias - y_0 e θ_0

[8]:
```
# Tamanho da populção - N
N = 500

# Valores iniciais
I0, R0 = 1, 0
S0 = N - I0

# Vetor de condições iniciais

y0 = S0, I0, R0

# Beta -  taxa de contato,
# r - taxa média de recuperação (in 1/dia).

theta0 = [1e-4,1e-2] # valores iniciais

# Definição do conjunto de equações diferencias não lineares que formam o modelo.

t = np.linspace(0, 1000, 1000)
```

3.3.5 Estimação de parâmetros

Para estimarmos os parâmetros do modelo β e **r**, vamos utilizar inicialmente o método de mínimos quadrados. Podemos então formular o problema a partir da Equação abaixo. Na Equação $y_m(k)$ representa o dado real em cada amostra k; $y_s(\theta, k)$ representa o **valor estimado** a partir da simulação do modelo para uma determinada amostra k e θ representa o vetor ed parâmetros $\theta = [\beta\ \ r]^T$.

$$min_\theta = \sum_{k=1}^{K} (y_m(k) - y_s(\theta, k))^2$$

A equação formula a pergunta: quais os valores de $beta$ e r que minizam o erro quadrático quando comparados com os dados reais.

[9]:
```
def ErroQuadratico(Sd,Id,Rd,y0,t,theta0):
    """ function to pass to optimize.leastsq
        The routine will square and sum the values returned by
        this function"""
    [S,I,R] = SIRsim(y0,t,theta0)
    erroS = S - Sd
    erroI = I - Id
    erroR = R - Rd
    EQ = np.concatenate([erroI,erroR])
    return EQ

def objetivo(p):
    return ErroQuadratico(Sd,Id,Rd,y0,t,p)
```

Minimização da função custo

[10]:
```
(c,kvg) = optimize.leastsq(objetivo,theta0)
print(c)
```

```
[9.93827391e-05 9.96628326e-03]
```

Visualização

[11]:
```
[Sa,Ia,Ra] = SIRsim(y0,t,c)

# Visualizando a evolução da Epidemia - S(t), I(t) e R(t)

show(column(p1,p2,p3))
```

Data type cannot be displayed: application/javascript, application/vnd.bokehjs_exec.v0+json

3.4.2 Selecionando um ano específico para análise

[4]:

```
selected_year = 1948

is_1948 = (data['time'].astype(int) == selected_year)
LD48 = data[is_1948]
LD48.head()

p = figure(tools=TOOLS, plot_width=600, plot_height=300)
p.line(LD48["time"], LD48["cases"], line_width=4, color="#8e44ad", line_alpha=0.9)

p.grid.grid_line_alpha = 0
p.ygrid.band_fill_color = "olive"
p.ygrid.band_fill_alpha = 0.1
p.yaxis.axis_label = "Casos"
p.xaxis.axis_label = "Data"

show(p)
```

Data type cannot be displayed: application/javascript, application/vnd.bokehjs_exec.v0+json

3.4.3 Os dados

Conhecemos o número de casos, os nascimentos e a população total. Podemos determinar os demais valores a partir da relação $S(t) + I(t) + R(t) = N$ onde **N** vamos considerar a população.

[5]:
```
s_array = LD48[["cases", "births", "pop","time"]].to_numpy()

Id = s_array[:,0]
Bd = s_array[:,1]
Sd = s_array[:,2] - Id + Bd
t  = s_array[:,3]
```

3.4.4 O problema

O conjunto de equações diferenciais que caracteriza o modelo é descrito abaixo. No modelo β - *representa a taxa de transmissão ou taxa efetiva de contato* e r - *a taxa de remoção ou recuperação*.

$$\begin{aligned} \frac{dS(t)}{dt} &= -\beta S(t)I(t) \\ \frac{dI(t)}{dt} &= \beta S(t)I(t) - \gamma I(t) \\ \frac{dR(t)}{dt} &= \gamma I(t) \end{aligned} \tag{3.1}$$

Gostaríamos de identificar quais parâmetros β e r resultam num melhor ajuste do modelo para os dados de **S**, **I** e **R**

[6]:
```
def SIRmodel(y, t, Beta, r):
    S, I = y
    Sdot = -Beta * S * I
    Idot = Beta * S * I  - r * I
    return Sdot, Idot

# Resolução da simulação - Escala temporal (dias)
```

3.4.5 Obtendo $y_s(\theta, k) = [S\ I\ R]$

O trecho a seguir retorna os valores sintetizados $y_s(\theta, k) = [S\ I\ R]$ representa o dado sintetizado a partir de um modelo sintetizado para uma determinada amostra k e θ representa o vetor ed parâmetros $\theta = [\beta\ \ r]^T$. A partir de uma condição inicial y_0.

[7]:
```
def SIRsim(y0, t, theta):
    Beta, r = theta[0], theta[1]
    ret = integrate.odeint(SIRmodel, y0, t, args=(Beta,r))
    S, I = ret.T
    return S, I
```

3.4.6 Condições inicias - y_0 e θ_0

[8]:
```
# Valores iniciais
I0 = Id[0]
S0 = Sd[0]

# Vetor de condições iniciais

y0 = S0, I0

# Beta -  taxa de contato
# r - taxa média de recuperação (in 1/dia).

# theta = [Beta, r]
theta0 = [1e-8, 1e-1] # valores iniciais

# Definição do conjunto de equações diferencias não lineares que formam o modelo.
t = (t - 1948) * 365
```

3.4.7 Estimação de parâmetros

Para estimarmos os parâmetros do modelo β e **r**, vamos utilizar inicialmente o método de mínimos quadrados. Podemos então formular o problema a partir da Equação abaixo. Na Equação $y_m(k)$ representa o dado real em cada amostra k; $y_s(\theta, k)$ representa o **valor estimado** a partir da simulação do modelo para uma determinada amostra k e θ representa o vetor ed parâmetros $\theta = [\beta \;\; r]^T$.

$$min_\theta = \sum_{k=1}^{K} (y_m(k) - y_s(\theta, k))^2$$

A equação formula a pergunta: quais os valores de $beta$ e r que minizam o erro quadrático quando comparados com os dados reais.

[9]:
```

3.5.2 Determinando os parâmetros - SIR

Nesta seção, iremos utilizar a biblioteca `models`, que concentra todas as funções dos modelos SIR desenvolvidos nas seções anteriores.

Para uma única cidade

[2]:
```
from models import *

# Getting the data for a particular city
dataset = data.where(data["city"] == "London").dropna()

# Creating the data for trainning
N = int(dataset["pop"].mean())
B = dataset["births"].to_numpy()
I = dataset["cases"].to_numpy()
S = dataset["pop"].to_numpy() - I + B
t = dataset["time"].to_numpy()

# Creating the SIR model
model = ss.SIR(pop=N, focus=["I"])

# Fitting the model on data
fit_data = model.fit_multiple(S, I, B, t,
                              r_sens=[1000,10], beta_sens=[100,100])

# Plotting the model results
fig = model.result_summary(
      out_plot=True,
      plot_size=[600,400])

from bokeh.plotting import show

show(fig)

3.6.3 Análise de um modelo com β variável no tempo

Uma outra forma de abordar a modelagme de dados é assumindo que a taxa de transmissão β é variante no tempo. Vamos, neste sentido, utilizar a abordagem elaborada por *Mark Pollicott, Hao Wang & Howard (Howie) Weiss em 2012 - Extracting the time-dependent transmission rate from infection data via solution of an inverse ODE problem*

Reescrevendo o conjunto de equações diferenciais que caracteriza o modelo é descrito abaixo. No modelo $:nbsphinx-math:*beta‘(t) - :nbsphinx-math:*text{representa a taxa de transmissão ou taxa efetiva de contato}‘ $ e $r -$ a taxa de remoção ou recuperação.

$$\frac{dS(t)}{dt} = -\beta(\mathbf{t})S(t)I(t)$$
$$\frac{dI(t)}{dt} = \beta(\mathbf{t})S(t)I(t) - rI(t)$$
$$\frac{dR(t)}{dt} = rI(t)$$

Gostaríamos de identificar quais parâmetros $\beta(t)$ e r resultam num melhor ajuste do modelo para os dados de **S**,**I** e **R**

Proposta de algoritmo para extração do $\beta(t)$ a partir dos dados

1. Interpolar os dados para suvizar eventuais variações gerando uma função $f(t)$

2. **Verificar a seguinte condição**: $\frac{f'(t)}{f(t)} > -r$. Neste algoritmo a taza de romação r é considerada constante.
3. Determinando a função $p(t) = \frac{f''(t)f(t) - f'^2(t)}{f(t)(f'(t) + rf(t))}$.
4. Escolhendo um valor inicial para $\beta(0)$ e determinando a integral $P(t) = \int_0^t p(\tau)d\tau$.
5. **Verificar a seguinte condição:** $\beta(0) < \frac{1}{\int_0^t e^{P(s)} f(s) ds}$.
6. O parâmetro $\beta(\mathbf{t})$ pode ser calculado por: $\beta(t) = \frac{1}{\frac{e^{-P(t)}}{\beta(0)} - e^{-P(t)} \int_0^t e^{P(s)} f(s) ds}$.

1) Interpolar os dados para suvizar eventuais variações gerando uma função $f(t)$

[5]:
```
import numpy as np
from scipy.interpolate import Rbf, UnivariateSpline

# Generating weights for polynomial function with degree =2
weights = np.polyfit(t_num, SPI, 2)
rbf = Rbf(t_num, SPI, function='gaussian')
spline = UnivariateSpline(t_num, SPI)
print(weights)

# Generating model with the given weights
model = np.poly1d(weights)

t_sim = np.linspace(t_num[0], t_num[-1], 100)

# Prediction on validation set
pred = model(t_sim)
pred_rbf = rbf(t_sim)

3.7.2 O problema

O conjunto de equações diferenciais que caracteriza o modelo é descrito abaixo. No modelo $:nbsphinx-math:*beta* '- *:nbsphinx-math:*text{representa a taxa de transmissão ou taxa efetiva de contato}' $ e r – a taxa de remoção ou recuperação.

$$\frac{dS(t)}{dt} = -\beta S(t)I(t)$$
$$\frac{dI(t)}{dt} = \beta S(t)I(t) - rI(t)$$
$$\frac{dR(t)}{dt} = rI(t)$$

Gostaríamos de identificar quais parâmetros β e r resultam num melhor ajuste do modelo para os dados de **S**,**I** e **R**

[5]:
```
# Importando o modelo SIR
from models import *

sir_model = ss.SIR(pop=N, focus=["I", "R"])
```

Data type cannot be displayed: application/javascript, application/vnd.bokehjs_load.v0+json

3.7.3 Estimando os parâmetros

Para estimarmos os parâmetros do modelo β e **r**, vamos utilizar inicialmente o método de mínimos quadrados. Podemos então formular o problema a partir da Equação abaixo. Na Equação $y_m(k)$ representa o dado real em cada amostra k; $y_s(\theta, k)$ representa o **valor estimado** a partir da simulação do modelo para uma determinada amostra k e θ representa o vetor ed parâmetros $\theta = [\beta \ \ r]^T$.

$$min_\theta = \sum_{k=1}^{K} (y_m(k) - y_s(\theta, k))^2$$

A equação formula a pergunta: quais os valores de $beta$ e r que minizam o erro quadrático quando comparados com os dados reais.

[12]:
```
import numpy as np

S = N - I - R

time = np.linspace(0, len(I), len(I))

```

3.8.4 Análise do uso do sistema de saúde

Nesta análise, mostramos o erro percentual do quanto antes do pico, conseguimos prever a quantidade de pessoas que realmente serão identificadas como infectadas, uma vez que $R(\infty)$ é a quantidade de pessoas recuperadas totais, daquelas que foram noficadas como infectadas no sistema de saúde. Desta forma segue o erro proporcional do erro a medida em que novos dados diários foram incluidos no modelo:

[34]:
```
x = range(start_day, len(I))
usage_error = [ 100 * abs(p*N - Rd[-1]) / Rd[-1] for p in saved_param['pop']]

fig9 = go.Figure()

fig9.add_trace(go.Scatter(
                    x=td[start_day:peak_pos],
                    y=usage_error[:peak_pos-start_day],
                    mode='lines',
                    name='Antes do pico',
                    line_shape='spline',
                    line = dict(color='royalblue', width=3),
                    hovertemplate="ϵ(%) = %{y:.0f}, <br> com %{x:.0f} dias de dados."))
fig9.add_trace(go.Scatter(
                    x=td[peak_pos:-1],
                    y=usage_error[peak_pos-start_day:-1],
                    mode='lines',
                    line_shape='spline',
                    name='Depois do pico',
                    line = dict(color='royalblue', width=3, dash='dot'),
                    hovertemplate="ϵ(%) = %{y:.0f}, <br> com %{x:.0f} dias de dados."))
fig9.add_trace(go.Scatter(
                    mode="markers", x=[peak_pos], y=[usage_error[peak_pos-start_day]],
                    marker_symbol="hexagram-dot", name="Momento do pico",

3.9.3 Monte Carlo

Nesta parte, faremos um teste aumentando a quantidade de amostras de treinamento e prevendo o momento do pico da epidemia a medida que mais dias são utilizados para treinamento. Esse estudo vai possibilitar a análise da certeza da previsão do pico da epidemia antes desse acontecer.

[13]:

```
saved_param = {'r':[], 'beta':[], 'pop':[]}
saved_prediction = []

start_day = 35
pred_t = np.array(range(int(td[-1]) + 120))

for i in range(start_day,len(I),1):

    dataset = dict(S=Sd[:i], I=Id[:i], R=Rd[:i])
    td_ = td[:i]

    # Create the model
    sir_model = ss.SIR(pop=N, focus=["S", "I", "R"], verbose = False)

    # Adjust the parameters
    sir_model.fit(dataset, td_,
                  search_pop=True,
                  pop_sens=[0.001,0.01],
                  beta_sens=[100000,100],
                  r_sens=[100000,100])
```

(continues on next page)

(continued from previous page)

```
    saved_param['beta'].append(sir_model.parameters[0])
    saved_param['r'].append(sir_model.parameters[1])
    saved_param['pop'].append(sir_model.parameters[2])

    saved_prediction.append(sir_model.predict((Sd[0],Id[0],Rd[0]), pred_t))
```

[27]:
```
import pickle

with open("./Italy_mc_runs.pickle", "wb") as handle:
    pickle.dump({"pars":saved_param, "pred":saved_prediction}, handle)
```

3.9.4 Análise do uso do sistema de saúde

Nesta análise, mostramos o erro percentual do quanto antes do pico, conseguimos prever a quantidade de pessoas que realmente serão identificadas como infectadas, uma vez que $R(\infty)$ é a quantidade de pessoas recuperadas totais, daquelas que foram noficadas como infectadas no sistema de saúde. Desta forma segue o erro proporcional do erro a medida em que novos dados diários foram incluidos no modelo:

[71]:
```
x = range(start_day, len(I))

usage_error = [ 100 * abs(p*N - Rd[-1]) / Rd[-1] for p in saved_param['pop']]

fig9 = go.Figure()

fig9.add_trace(go.Scatter(
                    x=td[start_day:peak_pos],
                    y=usage_error[:peak_pos-start_day],
                    mode='lines',
                    name='Antes do pico',
                    line_shape='spline',
                    line = dict(color='royalblue', width=3),
                    hovertemplate="ϵ(%) = %{y:.0f}, <br> com %{x:.0f} dias de dados."))
fig9.add_trace(go.Scatter(
                    x=td[peak_pos:-1],
                    y=usage_error[peak_pos-start_day:-1],
                    mode='lines',
                    line_shape='spline',
                    name='Depois do pico',
                    line = dict(color='royalblue', width=3, dash='dot'),
                    hovertemplate="ϵ(%) = %{y:.0f}, <br> com %{x:.0f} dias de dados."))
fig9.add_trace(go.Scatter(
                    mode="markers", x=[peak_pos], y=[usage_error[peak_pos-start_day]],
                    marker_symbol="hexagram-dot", name="Momento do pico",
                    marker_line_color="midnightblue", marker_color="lightskyblue",
                    marker_line_width=2, marker_size=15,
                    hovertemplate="Pico no dia %{x}, com um ϵ(%) = %{y:.0f}."))
fig9.add_trace(go.Scatter(
                    mode="markers", x=[td[-1]], y=[usage_error[-1]],
                    marker_symbol="triangle-right-dot", name="Valor atual",
                    marker_line_color="#a00037", marker_color="#ff5c8d",
                    marker_line_width=2, marker_size=15,
```

(continues on next page)

(continued from previous page)

```
                    hovertemplate="No dia %{x} da epidemia, <br> convergindo para ϵ(%)␣

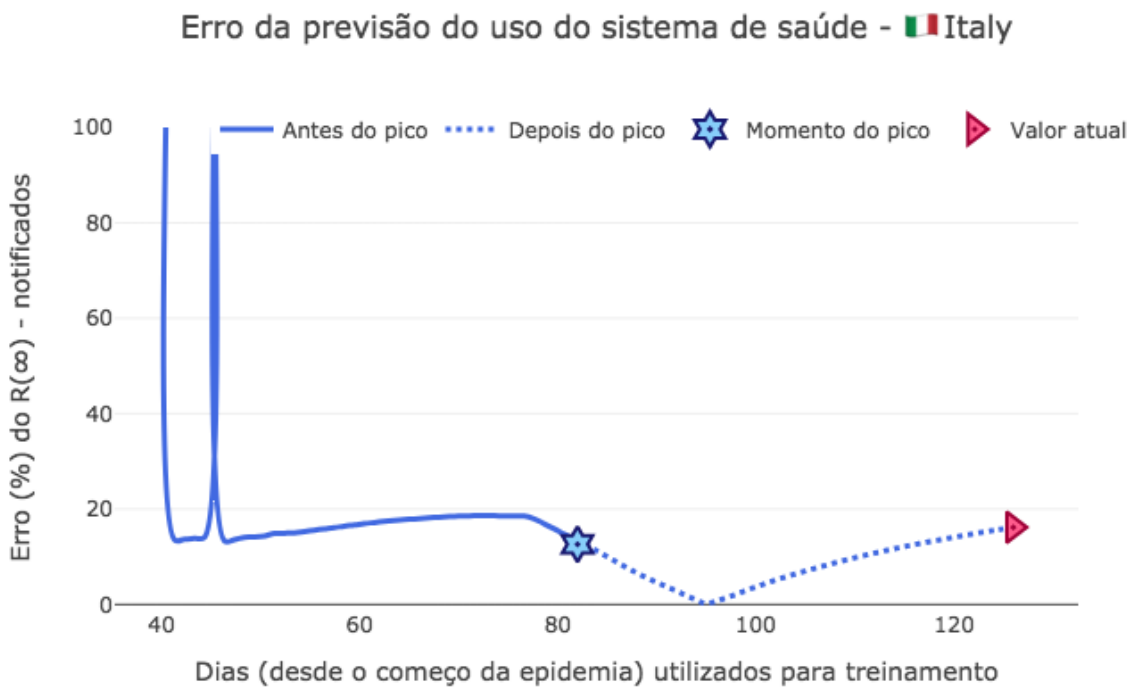
↪country['data']['name'])

fig9.show(renderer="png")
```



3.9.5 Visualizando as previsões de $I(t)$

Vamos analisar as previsões quando somente os dados antes do pico são fornecidos ao modelo, e as previões utilizando os dados após o pico:

[53]:

```
p2 = figure(plot_height=500,
            plot_width=600,
            tools="",
            toolbar_location=None,
            title="Evolução do COVID - " + country['data']['name'])

# Preparando o estilo
p2.grid.grid_line_alpha = 0
```

(continues on next page)

(continued from previous page)

```
p2.ygrid.band_fill_color = "olive"
p2.ygrid.band_fill_alpha = 0.1
p2.yaxis.axis_label = "Indivíduos"
p2.xaxis.axis_label = "Dias"

# Incluindo as curvas
p2.line(td, Id,
       legend_label="Infectados",
       line_cap="round", line_width=3, color="#c62828")

for data in saved_prediction[45:]:
    p2.line(pred_t[:len(td)], -data[1][:len(td)],
           legend_label="Previsão Infectados - Depois do pico",
           line_cap="round", line_dash="dashed", line_width=4, color="#ffa000", line_
↪alpha = 0.1)

for data in saved_prediction[:45]:
    p2.line(pred_t[:len(td)], -data[1][:len(td)],
           legend_label="Previsão Infectados - Antes do pico",
           line_cap="round", line_dash="dashed", line_width=4, color="#42a5f5", line_
↪alpha = 0.1)

# Colocando as legendas

3.10.3 Monte Carlo

Nesta parte, faremos um teste aumentando a quantidade de amostras de treinamento e prevendo o momento do pico da epidemia a medida que mais dias são utilizados para treinamento. Esse estudo vai possibilitar a análise da certeza da previsão do pico da epidemia antes desse acontecer.

[12]:

```
saved_param = {'r':[], 'beta':[], 'pop':[]}
saved_prediction = []

start_day = 45
pred_t = np.array(range(int(td[-1]) + 120))

for i in range(start_day, len(I)):

    dataset = dict(S=Sd[:i], I=Id[:i], R=Rd[:i])
    td_ = td[:i]

    # Create the model
    sir_model = ss.SIR(pop=N, focus=["S", "I", "R"], verbose = False)

    # Adjust the parameters
    sir_model.fit(dataset, td_,
                  search_pop=True,
                  pop_sens=[0.001,0.04],
                  beta_sens=[100,1000],
```

(continues on next page)

(continued from previous page)

```
                    r_sens=[100,100])

    saved_param['beta'].append(sir_model.parameters[0])
    saved_param['r'].append(sir_model.parameters[1])
    saved_param['pop'].append(sir_model.parameters[2])

    saved_prediction.append(sir_model.predict((Sd[0],Id[0], Rd[0]), pred_t))
```

[13]:
```
import pickle

with open("./Germany_mc_runs.pickle", "wb") as handle:
    pickle.dump({"pars":saved_param, "pred":saved_prediction}, handle)
```

3.10.4 Análise do uso do sistema de saúde

Nesta análise, mostramos o erro percentual do quanto antes do pico, conseguimos prever a quantidade de pessoas que realmente serão identificadas como infectadas, uma vez que $R(\infty)$ é a quantidade de pessoas recuperadas totais, daquelas que foram noficadas como infectadas no sistema de saúde. Desta forma segue o erro proporcional do erro a medida em que novos dados diários foram incluidos no modelo:

[41]:
```
x = range(start_day, len(I))
usage_error = [ 100 * abs(p*N - Rd[-1]) / Rd[-1] for p in saved_param['pop']]

fig9 = go.Figure()

fig9.add_trace(go.Scatter(
                    x=td[start_day:peak_pos],

3.10.5 Visualizando as previsões de $I(t)$

Vamos analisar as previsões quando somente os dados antes do pico são fornecidos ao modelo, e as previões utilizando os dados após o pico:

[17]:

```
visual_peak = 70

p2 = figure(plot_height=500,
            plot_width=600,
            tools="",
            toolbar_location=None,
            title="Evolução do COVID - " + country['data']['name'])
```

(continues on next page)

(continued from previous page)

```
# Preparando o estilo
p2.grid.grid_line_alpha = 0
p2.ygrid.band_fill_color = "olive"
p2.ygrid.band_fill_alpha = 0.1

3.11 epidemicModels

3.11.1 models package

Stochastic Search - Learning models

class models.stochastic_search.**SIR**(*pop=2000000, focus=['I', 'R'], algorithm='differential_evolution', simulation='discrete', stochastic_search=False, forced_search_pop=False, ode_full_output=False, verbose=True*)

Bases: object

This model concentrate all the developed algorithms to represent data driven SIR model. Using the Scipy default model structure.

cost_wrapper(**args*)

The method responsible for wrapping the cost function. This allows differential evolution algorithm to run with parallel processing.

Parameters ***args** (*tuple*) – cost function parameters

Returns the cost function outputs

Return type float

fit(*dataset, t, search_pop=True, Ro_bounds=None, pop_sens=[0.001, 0.0001], Ro_sens=[0.8, 15], D_sens=[5, 50], sigma_sens=None, mu_sens=[0.0001, 0.02], notified_sens=None, sample_ponder=None, optim_verbose=False, **kwargs*)

The method responsible for estimating a set of beta and r parameters for the provided data set. It assumes that in the data there is only one epidemic period.

Parameters

- **dataset** (*array*) – list with the respective arrays of Suceptible, Infected, Recovered and Deaths.
- **t** (*array*) – The time respective to each set of samples.
- **search_pop** (*bool*) – Flag to set the exposed population search, for better Suceptible extimation values. Default is `True`.
- **Ro_bounds** (*list*) – The bounds to build the constraints for `Ro = Beta / r`. With minimun and maximun values, respectivelly.
- **pop_sens** (*list*) – The sensibility (boudaries) for the proportion of `N` to be found by the pop parameters.
- **beta_sens** (*list*) – The beta parameter sensibility minimun and maximun boundaries, respectivelly. Default is `[100,100]`.
- **r_sens** (*list*) – The r parameter sensibility minimun and maximun boundaries, respectivelly. Default is `[100,1000]`.
- **sample_ponder** (*bool*) – The flag to set the pondering of the non informative recovered data.
- **optim_verbose** (*bool*) – If `True`, after fitting will show the optimization summary.
- ****kwargs** (*dict*) – The optimization search algorithms options.

fit_multiple(*Sd, Id, Bd, td, threshold_prop=1, cases_before=10, filt_estimate=False, filt_window=55, beta_sens=[100, 10], r_sens=[100, 10], out_type=0, **kwargs*)

The method responsible for estimating a set of beta and r parameters for each epidemy period existent in the provided dataset. It assumes that in the data there are several epidemic periods.

Parameters

- **Sd** (*array*) – Array with the suceptible data.
- **Id** (*array*) – Array with the infected data.
- **Bd** (*array*) – Array with the births data.
- **td** (*array*) – The time respective to each set of samples.
- **threshold_prop** (*float*) – The standard deviation proportion used as threshold for windowing. Default is `1.0`.
- **cases_before** (*int*) – The number of back samples to check for the initial window point. Default is `10`.
- **filt_estimate** (*bool*) – Flag to use filtered data to estimate the model parameters. Default is `False`.
- **filt_window** (*int*) – The window size used on the filtering technique, only if `filt_estimate=True`. Default is `55`.
- **beta_sens** (*list*) – The beta parameter sensibility minimun and maximun boundaries, respectivelly. Default is `[100,100]`.
- **r_sens** (*list*) – The r parameter sensibility minimun and maximun boundaries, respectivelly. Default is `[100,1000]`.
- **out_type** (*int*) – The output type, it can be `1` or `0`. Default is `0`.

Returns If the `out_type=0`, it returns a tuple with the estimated beta and r, estimated, with the year of each respective window. If *out_type=1* it returns the self.data of the model, a summary with all model information.

Return type tuple

monteCarlo_multiple(*Sd, Id, Bd, td, threshold_prop=1, cases_before=10, minimum_days=60, steps_indays=10, filt_estimate=False, filt_window=55, beta_sens=[1000, 10], r_sens=[1000, 10], out_type=0, **kwargs*)

The method responsible for estimating a set of beta and r parameters for each epidemy period existent in the provided dataset. It assumes that in the data there are several epidemic periods.

Parameters

- **Sd** (*array*) – Array with the suceptible data.
- **Id** (*array*) – Array with the infected data.
- **Bd** (*array*) – Array with the births data.
- **td** (*array*) – The time respective to each set of samples.
- **threshold_prop** (*float*) – The standard deviation proportion used as threshold for windowing. Default is `1.0`.
- **cases_before** (*int*) – The number of back samples to check for the initial window point. Default is `10`.
- **filt_estimate** (*bool*) – Flag to use filtered data to estimate the model parameters. Default is `False`.
- **filt_window** (*int*) – The window size used on the filtering technique, only if `filt_estimate=True`. Default is `55`.
- **beta_sens** (*list*) – The beta parameter sensibility minimun and maximun boundaries, respectivelly. Default is `[100,100]`.
- **r_sens** (*list*) – The r parameter sensibility minimun and maximun boundaries, respectivelly. Default is `[100,1000]`.
- **out_type** (*int*) – The output type, it can be `1` or `0`. Default is `0`.

Returns If the `out_type=0`, it returns a tuple with the estimated beta and r, estimated, with the year of each respective window. If *out_type=1* it returns the self.data of the model, a summary with all model information.

Return type tuple

predict(*initial*, *t*)

The function that uses the estimated parameters of the SIR model to predict the epidemy outputs (Suceptible, Infected and Recoverd) for the time samples provided, provided the initial conditions.

Parameters

- **initial** (*array*) – The initial values of the infected, suceptible and recovered data.
- **time** (*array*) – The time points to simulate the model.

Returns The values of the suceptible, infected and recovered, at time, respectivelly.

Return type tuple

result_summary(*out_plot=False, plot_size=[600, 400], save_results=False, folder_path='./', file_name='SIR_result_summary.png'*)

Method responsible for building a proper summary plot of the estimate process of the SIR model.

Parameters

- **out_plot** (*bool*) – Flag to output the bokeh.figure object.
- **plot_size** (*list*) – List with the plot size as *[width, height]*.
- **save_results** (*bool*) – Flag to save the results as a .png image.
- **folder_path** (*string*) – The path to the folder the user wants to save resulted image.
- **file_name** (*string*) – The name of the resulted image that will be saved.

Returns If *out_plot=True*, it returns a bokeh.figure object with the builded plots.

Return type bokeh.figure

simulate(*initial*, *time*, *theta*)

The function that simulate the differential SIR model, by computing the integration of the differential equations.

Parameters

- **initial** (*array*) – The initial values of the infected and suceptible data.
- **time** (*array*) – The time points to simulate the model.
- **theta** (*array*) – The Beta parameter, and r parameter, respectivelly.

Returns The values of the suceptible and infected, at time, respectivelly.

Return type tuple

models.stochastic_search.**findEpidemyBreaks**(*cases*, *threshold_prop=1.0*, *cases_before=10*)

The function responsible for determining the initial and final points of the epidemies windows.

Parameters

- **cases** (*array*) – The array with the cases values along time.
- **threshold_prop** (*float*) – The standard deviation proportion used as threshold for windowing. Default is *1.0*.
- **cases_before** (*int*) – The number of back samples to check for the initial window point. Default is *10*.

Returns With the list of window's starting points and window's final points, respectively.

Return type tuple

Cost Functions

models.cost_functions.**PrintException**(*e*)

models.cost_functions.**cost_NSIR**(*self*, *pars*, *dataset*, *initial*, *t*, *w*)

models.cost_functions.**cost_SEIR**(*self*, *pars*, *dataset*, *initial*, *t*, *w*)

The function to compute the error to guide the learning algorithm. It computes the quadratic error.

Parameters

- **pars** (*tuple*) – Tuple with Beta and r parameters, respectivelly.
- **dataset** (*list*) – The dataset with the respective S, I and R arrays.
- **initial** (*array*) – The initial values of suceptible and infected, respectivelly.
- **t** (*array*) – The time respective to each sample.

- **w** (*array*) – The weight respective to the suceptible and infected errors.

Returns The sum of the quadratic error, between simulated and real data.

Return type float

models.cost_functions.**cost_SIR**(*self*, *pars*, *dataset*, *initial*, *t*, *w*)
The function to compute the error to guide the learning algorithm. It computes the quadratic error.

Parameters

- **p** (*tuple*) – Tuple with Beta and r parameters, respectivelly.
- **S** (*array*) – The suceptible data values.
- **I** (*array*) – The infected data values.
- **initial** (*array*) – The initial values of suceptible and infected, respectivelly.
- **t** (*array*) – The time respective to each sample.
- **w** (*array*) – The weight respective to the suceptible and infected errors.

Returns The sum of the quadratic error, between simulated and real data.

Return type float

models.cost_functions.**cost_SIRD**(*self*, *pars*, *dataset*, *initial*, *t*, *w*)
The function to compute the error to guide the learning algorithm. It computes the quadratic error.

Parameters

- **p** (*tuple*) – Tuple with Beta and r parameters, respectivelly.
- **S** (*array*) – The suceptible data values.
- **I** (*array*) – The infected data values.
- **initial** (*array*) – The initial values of suceptible and infected, respectivelly.
- **t** (*array*) – The time respective to each sample.
- **w** (*array*) – The weight respective to the suceptible and infected errors.

Returns The sum of the quadratic error, between simulated and real data.

Return type float

models.cost_functions.**cost_dSIR**(*self*, *pars*, *dataset*, *initial*, *t*, *w*)
The function to compute the error to guide the learning algorithm. It computes the quadratic error.

Parameters

- **p** (*tuple*) – Tuple with Beta and r parameters, respectivelly.
- **S** (*array*) – The suceptible data values.
- **I** (*array*) – The infected data values.
- **initial** (*array*) – The initial values of suceptible and infected, respectivelly.
- **t** (*array*) – The time respective to each sample.
- **w** (*array*) – The weight respective to the suceptible and infected errors.

Returns The sum of the quadratic error, between simulated and real data.

Return type float

Differential Models

models.differential_models.**NSIR**(*self*, *y*, *t*, *beta*, *r*, *betan*, *alpha*, *rn*, **args*)

models.differential_models.**SEIR**(*self*, *y*, *t*, *Beta*, *r*, *sigma*)

The function that computes the diferential set of equations of the SEIR Epidemic Model.

Parameters

- **y** (*tuple*) – Tuple with the suceptible and infected data.
- **t** (*array*) – The time respective to each y set of samples.
- **Beta** (*float*) – The Beta parameter.
- **r** (*float*) – The r parameter.
- **sigma** (*float*) – The sigma parameter.

Returns The derivative of the suceptible and infected data.

Return type tuple

models.differential_models.**SIR**(*self*, *y*, *t*, *parameters*, **args*)

The function that computes the diferential set of equations of the SIR Epidemic Model.

Parameters

- **y** (*tuple*) – Tuple with the suceptible and infected data.
- **t** (*array*) – The time respective to each y set of samples.
- **Beta** (*float*) – The Beta parameter.
- **r** (*float*) – The r parameter.

Returns The derivative of the suceptible and infected data.

Return type tuple

models.differential_models.**SIRD**(*self*, *y*, *t*, *parameters*)

The function that computes the diferential set of equations of the SIRD Epidemic Model.

Parameters

- **y** (*tuple*) – Tuple with the suceptible and infected data.
- **t** (*array*) – The time respective to each y set of samples.
- **Beta** (*float*) – The Beta parameter.
- **r** (*float*) – The r parameter.
- **mi** (*float*) – The mi parameter.

Returns The derivative of the suceptible and infected data.

Return type tuple
